背景: Plasminogen activator inhibitor-2 (placental PAI) is a coagulation factor that inactivates tPA and urokinase. It is present in most cells, especially monocytes/macrophages. PAI-2 exists in two forms, a 60-kDa extracellular glycosylated form and a 43-kDa intracellular form. It is present only at detectable quantities in blood during pregnancy, as it is produced by the placenta, and may explain partially the increased rate of thrombosis during pregnancy.

Immunohistochemistry analysis of paraffin embedded Human liver cancer tissue using 217668 (SERPINB2 Antibody) at a dilution of 1/20 (Secreted).

In comparison with the IHC on the left, the same paraffin-embedded Human liver cancer tissue is first treated with the fusion protein and then with 217668 (Anti-SERPINB2 Antibody) at dilution 1/20.
